

Load Balancing Approach for Adaptive Bitrate Streaming in ICN

Divyashri Bhat, Cong Wang,
Amr Rizk, Michael Zink

June 16th, 2015

- Load balancing is inherent in the NDN paradigm as content is populated and cached on router nodes across the network.
- In contrast, load balancing in TCP/IP networks is often carried out using dedicated infrastructure in the sense of TCP termination points and load balancing schedulers.
- NDN comes with organic load balancing

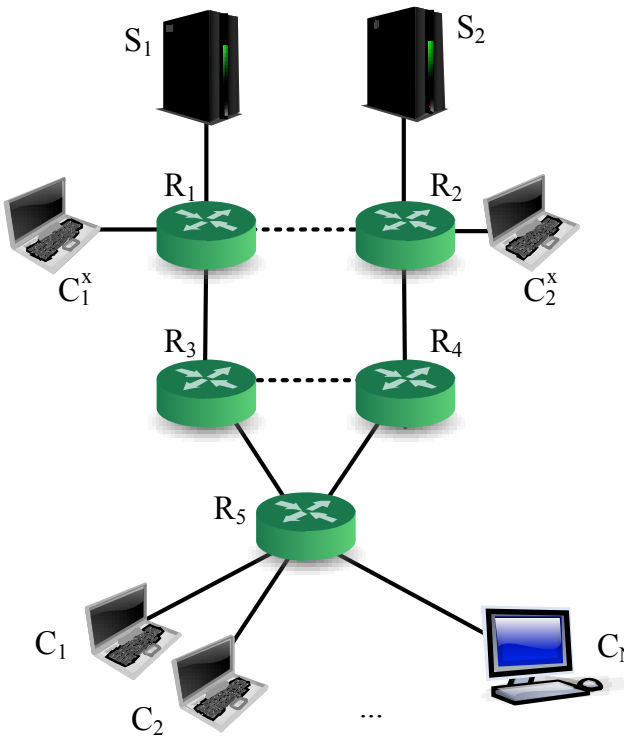

P[interest admitted to PIT]

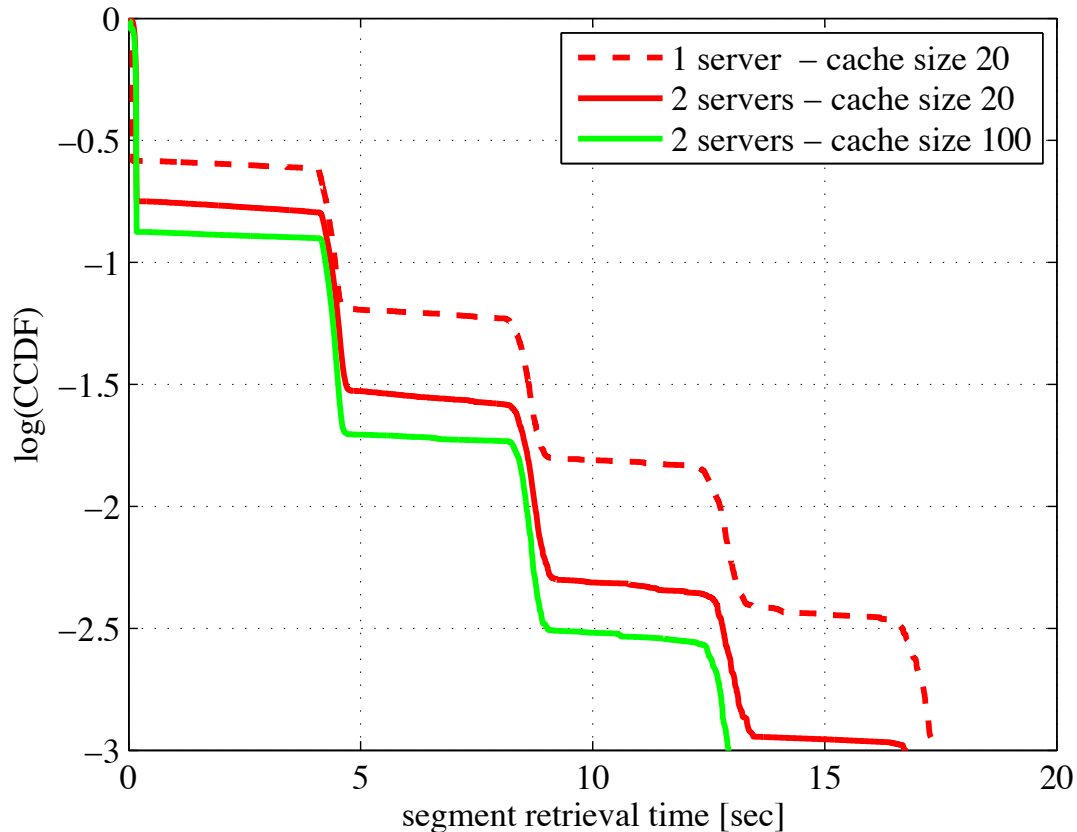

- L_p – Dropping interests is viable
- L_B – Interests will be dropped

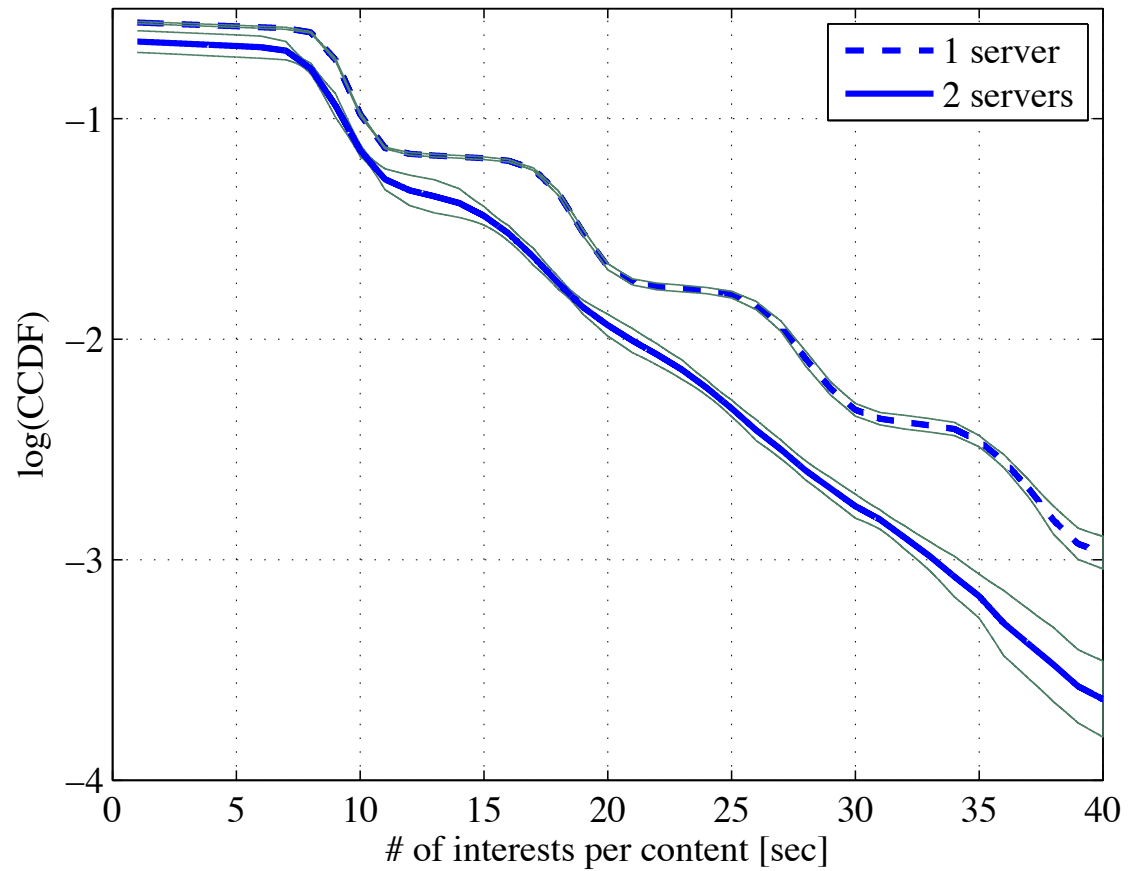

- Average acceptance rate = $(1 - e^{-\lambda})$, $\lambda = 4$

- ndnSIM 2.0, based on NS-3
- Delay=10ms, capacity=10Mbps for all links besides R_i-S_i ,
- R_i-S_i capacity=5Mbps, output queue=50 frames
- Default LRU cache (20 contents max.)
- 10 independent clients on R_5 , 100 interests per second
- $L_p=0, L_B=1$
- Crosstraffic C_1, C_2 , Poisson process, 500pps

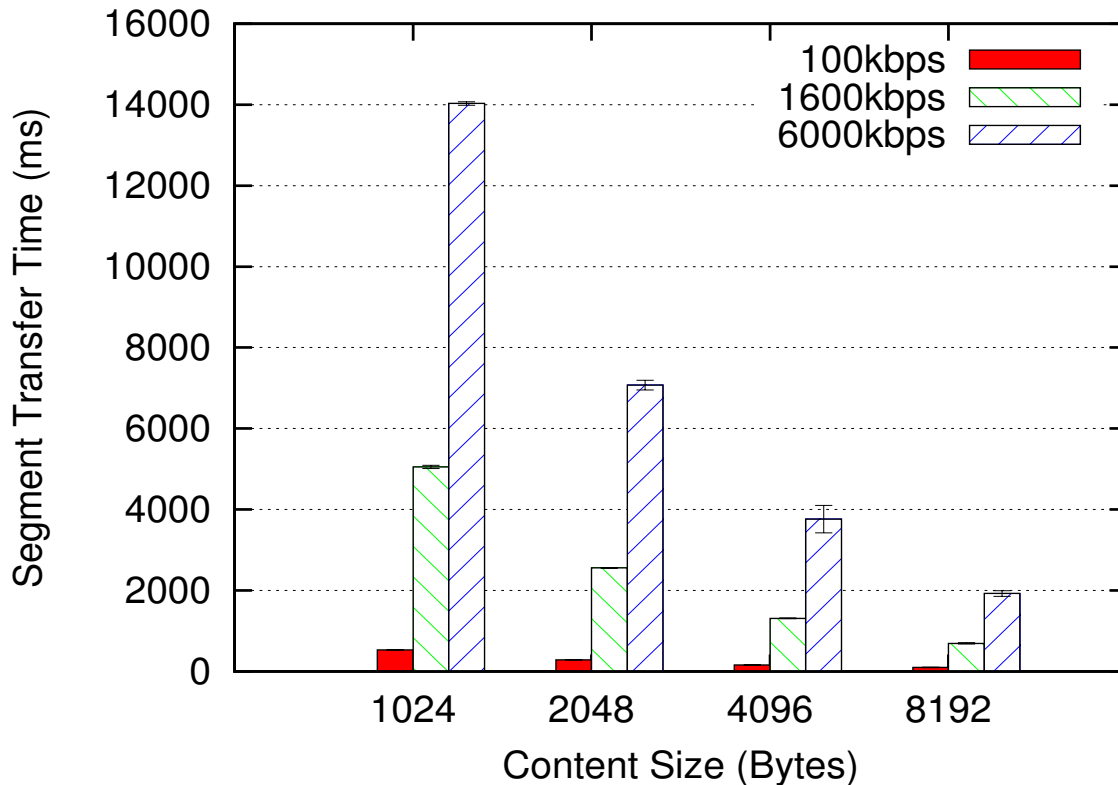

- Remove right branch for 1 server case
- R_1-S_1 capacity 10 Mbps
- Segment retrieval time = reception of content – send of interest request

MM Streaming Performance over NDN

- Measurements performed in actual GENI testbed
- Impact of content size
- Estimating available bandwidth
- NDN over Ethernet

- Segment transfer time decreases with increasing content size
- Affect of multiple coexisting content sizes?

- Multi-sourcing content
- Disjoint paths
- *Cache size = 80 contents*
- *Segment = 167 contents*
- Segment transfer times are smeared average of oscillating content transfer times

- Investigated load balancing in NDN
- Substantially reduces segment retrieval time
- Real-world testbed experiments of native NDN over Ethernet
- Two-layered version of oscillation problem in case of multi-sourcing
